Electromagnetic waves are an inherent part of all plasmas – laboratory fusion plasmas or astrophysical plasmas. The conventional methods for studying properties of electromagnetic waves rely on discretization of Maxwell equations suitable for implementing on classical, present day, computers. The traditional methodology is not efficient for quantum computing implementation – a future computational source offering a tantalizing possibility of enormous speed up and a significant reduction in computational cost. This paper addresses two topics relevant to implementing Maxwell equations on a quantum computer. The first is on formulating a quantum Schrödinger representation of Maxwell equations for wave propagation in a cold, inhomogeneous, magnetized plasma. This representation admits unitary, energy preserving, evolution and conveniently lends itself to appropriate discretization for a quantum computer. Riding on the coattails of these results, the second topic is on developing a sequence of unitary operators which form the basis for a qubit lattice algorithm (QLA). The QLA, suitable for quantum computers, can be implemented and tested on existing classical computers for accuracy as well as scaling of computational time with the number of available processors. In order to illustrate the QLA for Maxwell equations, results are presented from a time evolving, full wave simulation of propagation and scattering of an electromagnetic wave packet by non-dispersive dielectric medium localized in space.

I. INTRODUCTION

Propagation of electromagnetic waves in thermonuclear fusion plasmas is one of the most significant fields of research in the pursuit for magnetic fusion. In magnetic confinement experiments, electromagnetic waves play a vital role in plasma temperature control, localized non-inductive current drive, heating, and plasma instability control. Therefore, there is an utmost need for understanding the physics and mechanics of wave propagation and scattering inside an inhomogeneous magnetized plasma to enable the optimization for fusion applications.

While the bedrock for the theoretical and analytical studies of wave propagation in plasmas has long been established,^{1,2} penetrating into the complex processes that occur in plasmas and unraveling their physics require a computational treatment. To that end, taking into consideration the aforementioned importance of electromagnetic wave propagation in plasmas, a plethora of computational tools have been developed,^{3–5} ranging from ray-tracing methods to full-wave simulations along with different domains of application.

However, solving the mathematical and physical problem of wave propagation in an actual fusion device poses

a challenge even for the most advanced supercomputers. With classical computers eventually reaching their limits and fusion research heavily relying on computational results we motivate a shift in the traditional computational methods, engaging the modern and uprising quantum technologies and quantum computing in particular.

Quantum computing is one of those computational pathways that can yield faster computations than those achieved on a classical computer,^{6,7} the so called quantum advantage, and has gained significant attention in the plasma physics community. Considerations on general applications in plasma simulation can be found in Ref.[8], whereas a fusion oriented review of possible quantum computing applications is Ref.[9]. In Refs. [10] and [11] the authors exploit the Quantum Signal Processing (QSP) protocol¹² for simulation of electrostatic Landau damping and wave propagation in a cold fluid plasma respectively. In addition, a quantum computing treatment for Vlasov equation with collisions has been presented in Ref. [13]. Finally, a comprehensive review on quantum computing applications in plasmas can be found in Ref.[14].

In this paper, we examine Maxwell equations for wave propagation in cold, inhomogeneous, magnetized plasma amendable to quantum computing without tackling the question of computational advantage over the classical methods. Quantum computers are restricted to unitary

^{a)}Electronic mail: stkoukoutsis@mail.ntua.gr

operations following the physical laws of closed quantum systems. Thus, the first step towards a quantum implementation is to reformulate Maxwell equations as a quantum Schrodinger equation with Hermitian structure, extending the results of [15] to encompass the dispersive nature of cold magnetized plasma. Then, the second challenge entails decomposing the relevant unitary operator of evolution into a product sequence of unitary operators that can be encoded efficiently on a quantum computer. We accomplish this by leveraging the tensor product structure of the Hamiltonian, deriving a Trotterized unitary sequence that constitutes the basis for a latter Qubit Lattice Algorithm (QLA). The scaling of the quantum encoded QLA has been recently reported^{15–17} to favor quantum implementation on real quantum hardware.

Qubit lattice algorithms along with its predecessors have found extensive computational applications in the fields of Maxwell equations,^{18–23} non-linear optics^{24,25} and quantum simulations.^{15,26–28}

To assess the capabilities of QLA we present full-wave simulation results from propagation and scattering of an electromagnetic wave packet in a reduced case of our formulation,²³ for a localized inhomogeneous, scalar dielectric. Such wave packet structures in plasma are related to the finite spatial extent applied RF waves that are routinely used for plasma heating. Although these simulations are implemented on classical supercomputers they can be directly transferred to quantum computers, acting as a precursor and validation factor for the proposed QLA generalization into cold magnetized plasma in the near term future.

This paper is structured in two main sections. Section II sets up the theoretical formulation of Maxwell equations as a quantum Schrodinger equations, following up a decomposition of the evolution operator into a convenient unitary product sequence for QLA discretization along with the pertinent discussion on complexity. In Sec.IIA an augmented form of Maxwell equations in magnetized plasma is presented, serving as a stepping stone for the construction of a Schrodinger-Maxwell equation with unitary evolution in Sec.IIB. The importance of initial and boundary conditions is discussed in Sec. IIC. Decomposition of the established unitary evolution in a product formula of simple unitary operators based on Trotterization is the main subject of Sec.IID. A simple complexity analysis is performed in Sec.IIE regarding the scaling of QLA implementation in quantum hardware, indicating a polynomial scaling with the number of qubits required for the QLA discretization. Then, a commentary section IIF follows, containing perspectives on the QLA implementation for wave propagation and scattering in the cold plasma. Section III serves as an indicator of QLA capabilities for the future implementation in the cold plasma case studied in Sec.II. Specifically, in sections IIIA and IIIB we present the algorithmic scheme of QLA along with some initial value simulations for full-wave scattering of an electromagnetic wave-packet from

two-dimensional (2D) scalar, non-dispersive inhomogeneous dielectric objects. In particular, we contrast the different scattering characteristics from a local cylindrical dielectric with strong gradients in the finite boundary layer between the dielectric and vacuum, with that scattering from a local conic dielectric with weak boundary layer gradients in the refractive index. Finally, in Sec.IV we discuss our results along with the next necessary steps for an actual QLA implementation in the near future.

II. QUANTUM IMPLEMENTATION OF MAXWELL EQUATIONS IN COLD MAGNETIZED PLASMA

For a non-dispersive, tensorial and inhomogeneous medium, Maxwell equations can be written as a Schrodinger equation with unitary evolution¹⁵

$$i\frac{\partial\psi}{\partial t} = \hat{D}_\rho\psi, \quad \hat{D}_\rho = \hat{D}_\rho^\dagger, \quad \psi(\mathbf{r}, 0) = \psi_0, \quad (1)$$

under a Dyson transformation $\hat{\rho}$ on the electromagnetic fields $\mathbf{u} = (\mathbf{E}, \mathbf{H})^T$, with $\psi = \hat{\rho}\mathbf{u}$. In particular, the Hermitian operator \hat{D}_ρ

$$\hat{D}_\rho = \hat{\rho}\hat{D}\hat{\rho}^{-1} = \hat{\rho}\hat{W}^{-1}(\mathbf{r})\hat{M}\hat{\rho}^{-1}, \quad (2)$$

with

$$\hat{M} = i \begin{bmatrix} 0_{3\times 3} & \nabla \times \\ -\nabla \times & 0_{3\times 3} \end{bmatrix}, \quad \hat{W} = \begin{bmatrix} \epsilon(\mathbf{r}) & 0_{3\times 3} \\ 0_{3\times 3} & \mu(\mathbf{r}) \end{bmatrix}. \quad (3)$$

In Eq.(3) the \hat{M} operator is the Maxwell curl operator and the Hermitian, positive definite \hat{W} matrix represents the constitutive relations of the medium. The explicit form of the Dyson map $\hat{\rho}$ depends on the structure of the material matrix \hat{W} : $\hat{\rho} = \sqrt{\hat{W}}$.

On the other hand, the cold magnetized plasma as a dielectric medium is characterized by dispersion. This translates into a frequency dependent permittivity matrix $\tilde{\epsilon}(\omega)$. Following the Stix notation¹,

$$\tilde{\epsilon}(\omega) = \begin{bmatrix} S & -iD & 0 \\ iD & S & 0 \\ 0 & 0 & P \end{bmatrix} \quad (4)$$

with

$$\begin{aligned} S &= \epsilon_0 \left(1 - \sum_{j=i,e} \frac{\omega_{pj}^2}{\omega^2 - \omega_{cj}^2} \right) \\ D &= \epsilon_0 \sum_{j=i,e} \frac{\omega_{cj}\omega_{pj}^2}{\omega(\omega^2 - \omega_{cj}^2)} \\ P &= \epsilon_0 \left(1 - \sum_{j=i,e} \frac{\omega_{pj}^2}{\omega^2} \right). \end{aligned} \quad (5)$$

The definition of elements (5) in the Stix permittivity tensor is taken for a two-species, ions (i) and electrons (e), plasma with inhomogeneous plasma frequency

$\omega_{pj}^2(\mathbf{r}) = \frac{n_j(\mathbf{r})q_j^2}{m_j\epsilon_0}$ and cyclotron frequency $\omega_{cj} = \frac{q_j B_0}{m_j}$. The homogeneous magnetic field B_0 is along the z axis and m_j, q_j are the mass and charge of the j -species respectively. $n_j(\mathbf{r})$ is the j^{th} species density.

A. Maxwell equations in temporal domain

In contrast to the optical response case, the temporal domain transformation of $\tilde{\epsilon}(\omega)$ is expressed through a convolution integral. As a result, the temporal domain, constitutive relations for a cold magnetized plasma are

$$\mathbf{d} = \hat{W}_0 \mathbf{u} + \frac{1}{2\pi} \int_0^t \int_{-\infty}^{\infty} (\tilde{\epsilon}(\omega) - \epsilon_0 I_{3 \times 3}) e^{-i\omega(t-\tau)} \mathbf{E}(\mathbf{r}, \tau) d\omega d\tau, \quad (6)$$

with $\mathbf{d} = (\mathbf{D}, \mathbf{B})^T$. The matrix \hat{W}_0 represents the optical response, as in Eq.(3), but now only that of the vacuum.

Evaluation of the inner integral term in Eq. (6) requires the Plemelj formula¹ to yield

$$\mathbf{d} = \hat{W}_0 \mathbf{u} + \int_0^t \hat{K}(t-\tau) \mathbf{E}(\mathbf{r}, \tau) d\tau, \quad (7)$$

with the inhomogeneous susceptibility kernel $\hat{K}(t)$

$$\hat{K}(t) = \epsilon_0 \sum_{j=i,e} \begin{bmatrix} \frac{\omega_{pj}^2}{\omega_{cj}} \sin \omega_{cj} t & \frac{\omega_{pj}^2}{\omega_{cj}} (\cos \omega_{cj} t - 1) & 0 \\ \frac{\omega_{pj}^2}{\omega_{cj}} (1 - \cos \omega_{cj} t) & \frac{\omega_{pj}^2}{\omega_{cj}} \sin \omega_{cj} t & 0 \\ 0 & 0 & \omega_{pj}^2 t \end{bmatrix}. \quad (8)$$

From the expressions (7) and (8), Maxwell equations for a cold magnetized plasma now take the form

$$i \frac{\partial \mathbf{u}}{\partial t} = W_0^{-1} \hat{M} \mathbf{u} - i \int_0^t \frac{\partial \hat{G}(t-\tau)}{\partial t} \mathbf{u}(\mathbf{r}, \tau) d\tau \quad (9)$$

where

$$\frac{\partial \hat{G}(t)}{\partial t} = \begin{bmatrix} \frac{1}{\epsilon_0} \frac{\partial \hat{K}}{\partial t} & 0_{3 \times 3} \\ 0_{3 \times 3} & 0_{3 \times 3} \end{bmatrix}, \quad \frac{1}{\epsilon_0} \frac{\partial \hat{K}}{\partial t} = \sum_{j=i,e} \omega_{pj}^2(\mathbf{r}) \begin{bmatrix} \cos \omega_{cj} t & -\sin \omega_{cj} t & 0 \\ \sin \omega_{cj} t & \cos \omega_{cj} t & 0 \\ 0 & 0 & 1 \end{bmatrix}. \quad (10)$$

B. Schrodinger representation

Returning back to $\tilde{\epsilon}(\omega)$ in Eq. (4), its Hermitian structure ensures that the conductivity current does not produce dissipation inside the plasma, i.e the cold magnetized plasma is a lossless dispersive dielectric. Hence, it is possible to construct a Schrodinger representation of Maxwell equations (9) that admit unitary evolution corresponding to electromagnetic energy conservation. Such mathematical representations of Maxwell equations for lossless dispersive media are well studied in the literature^{29,30}.

Defining the total conductivity current density \mathbf{J}_c as

$$\mathbf{J}_c = \int_0^t \frac{\partial \hat{K}}{\partial t} \mathbf{E}(\mathbf{r}, \tau) d\tau = \mathbf{J}_{ce} + \mathbf{J}_{ci}, \quad (11)$$

we exploit the rotational symmetry of $\frac{\partial \hat{K}}{\partial t}$ in Eq.(10) to

reformulate Maxwell equations (9) as

$$\begin{aligned} i \frac{\partial \mathbf{E}}{\partial t} &= \frac{i}{\epsilon_0} \nabla \times \mathbf{H} - \frac{i}{\epsilon_0} \mathbf{J}_c, \\ i \frac{\partial \mathbf{H}}{\partial t} &= -\frac{i}{\mu_0} \nabla \times \mathbf{E}, \\ i \frac{\partial \mathbf{J}_{cj}}{\partial t} &= i \epsilon_0 \omega_{pj}^2(\mathbf{r}) \mathbf{E} + \omega_{cj} \hat{S}_z \mathbf{J}_{cj}, \quad j = i, e. \end{aligned} \quad (12)$$

The set of equations (12) represent the augmented Maxwell system which self-consistently describes the behaviour of electromagnetic fields inside a cold magneto-plasma. We point out that Eq.(12) is the basis for FDTD simulations,³¹ but for a stationary plasma. The Hermitian matrix \hat{S}_z ,

$$\hat{S}_z = \begin{bmatrix} 0 & -i & 0 \\ i & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \quad (13)$$

represents the projection of spin-1 onto the z -axis.

To obtain an explicit Schrodinger representation of Eq.(12) we apply a Dyson transformation¹⁵,

$$\hat{\rho} = \text{diag}(\epsilon_0^{1/2} I_{3 \times 3}, \mu_0^{1/2} I_{3 \times 3}, \frac{1}{\epsilon_0^{1/2} \omega_{pi}} I_{3 \times 3}, \frac{1}{\epsilon_0^{1/2} \omega_{pe}} I_{3 \times 3}) \quad (14)$$

resulting in

$$i\frac{\partial}{\partial t} \begin{bmatrix} \epsilon_0^{1/2} \mathbf{E} \\ \mu_0^{1/2} \mathbf{H} \\ \frac{1}{\epsilon_0^{1/2} \omega_{pi}} \mathbf{J}_{ci} \\ \frac{1}{\epsilon_0^{1/2} \omega_{pe}} \mathbf{J}_{ce} \end{bmatrix} = \begin{bmatrix} 0_{3 \times 3} & ic \nabla \times & -i\omega_{pi} & -i\omega_{pe} \\ -ic \nabla \times & 0_{3 \times 3} & 0_{3 \times 3} & 0_{3 \times 3} \\ i\omega_{pi} & 0_{3 \times 3} & \omega_{ci} \hat{S}_z & 0_{3 \times 3} \\ i\omega_{pe} & 0_{3 \times 3} & 0_{3 \times 3} & \omega_{ce} \hat{S}_z \end{bmatrix} \begin{bmatrix} \epsilon_0^{1/2} \mathbf{E} \\ \mu_0^{1/2} \mathbf{H} \\ \frac{1}{\epsilon_0^{1/2} \omega_{pi}} \mathbf{J}_{ci} \\ \frac{1}{\epsilon_0^{1/2} \omega_{pe}} \mathbf{J}_{ce} \end{bmatrix} \Leftrightarrow i\frac{\partial \psi}{\partial t} = \hat{D} \psi. \quad (15)$$

It should be noted that we have switched from using the Riemann-Silberstein-Weber³² field representation to the vacuum field representation, and the plasma inhomogeneity is now thrust into the source terms $\mathbf{J}_{ci}, \mathbf{J}_{ce}$ through the species plasma frequencies $\omega_{pj}(\mathbf{r})$. Additionally, Eq.(15) can be easily extended to incorporate different ions species by adding the respective ion-species current components in the stave vector ψ . In realistic fu-

sion experiments there will be hydrogen, deuterium and tritium ions, so their contribution must be included in Eq.(15) for a complete description of the total inhomogeneity profiles.

Under suitable Dirichlet boundary conditions the operator \hat{D} in the Schrodinger-Maxwell Eq.(15) is Hermitian. As a result, the evolution operator $\hat{U} = e^{-it\hat{D}}$ is unitary and corresponds to the conservation of an extended electromagnetic energy $E(t)$ through the inner product,

$$E(t) = \langle \psi | \psi \rangle = \int_{\Omega} \left(\epsilon_0 |\mathbf{E}|^2 + \frac{|\mathbf{B}|^2}{\mu_0} \right) d\mathbf{r} + \int_{\Omega} \left(\frac{|\mathbf{J}_{ci}|^2}{\epsilon_0 \omega_{pi}^2(\mathbf{r})} + \frac{|\mathbf{J}_{ce}|^2}{\epsilon_0 \omega_{pe}^2(\mathbf{r})} \right) d\mathbf{r} = E(0) = \int_{\Omega} \left(\epsilon_0 |\mathbf{E}_0|^2 + \frac{|\mathbf{B}_0|^2}{\mu_0} \right) d\mathbf{r}, \quad \Omega \subset \mathbb{R}^3. \quad (16)$$

The extended electromagnetic energy Eq.(16) consists of two terms. The first term is the standard electromagnetic energy in a vacuum whereas the second term reflects the energy associated with the cold plasma response. We have denoted with \mathbf{E}_0 and \mathbf{B}_0 the initial values of the electromagnetic fields. Notice that due to the causality constraint in the plasma response, the initial values of the conductivity currents according to Eq.(11) are zero, $\mathbf{J}_{ce,i}(t \leq 0) = 0$.

A subtlety related with the extended electromagnetic energy (16) is the smoothness of $E(t)$ because of the Laplace Transform in Eq.(6). As a result, even for resonant frequencies $\omega = \omega_{cj}$ we obtain a bounded dispersive electromagnetic energy $E_{disp}(t) \leq E(0)$. Thus, it is possible to quantify the resonant energization for each plasma population without considering resonant wave-particle interactions or perturbative approximations for the RF field.

C. Initial and boundary conditions

In this section we will restate our problem comparing the imposed mathematical conditions with the ones in a plasma fusion device.

The plasma as a dielectric is considered to be confined inside a volume $\Omega \subset \mathbb{R}^3$ with a boundary surface $\partial\Omega$. By selecting the boundary condition

$$\mathbf{n} \times \mathbf{E} = 0, \quad \text{on } \partial\Omega, \quad (17)$$

the ‘‘Hamiltonian operator’’ \hat{D} in the Maxwell-Schrodinger equation (15) is Hermitian so the standard

quantum-mechanical analogies are present. In fusion devices, the plasma is confined by a vacuum vessel at which the Perfect Electric Conductor (PEC) boundary condition (17) no longer holds due to electromagnetic losses in the walls. Alteration of the PEC boundary condition results in the non-Hermiticity of the operator \hat{D} and subsequently, a break in the unitary evolution. In this case, the quantum simulation of the dynamics becomes troublesome. A solution has been proposed in Ref.[33] where instead of the quantum simulation of the Maxwell dynamics, the linear system of equations is solved through quantum singular value decomposition as a boundary value problem. This approach could run into some difficulties as one moves to 2D and 3D plasma wave propagation. Alternatively, one could resort to some dilation by embedding the subsystem into a higher dimensional Hilbert space and thereby recover unitarity within this higher dimensional space.

For completeness, one could eventually introduce into the set of equations (12) the effect of an antenna by coupling the Faraday equation with a monochromatic oscillator¹¹ $\mathbf{Q}(\mathbf{r}, t) = \mathbf{Q}_a(\mathbf{r}_a) e^{-i\omega_a t}$ with frequency ω_a . The subscript a denotes the antenna-related quantities. In that way, the Faraday equation in (15) is augmented by

$$i\frac{\partial(\mu_0^{1/2} \mathbf{H})}{\partial t} = -ic \nabla \times (\epsilon_0^{1/2} \mathbf{E}) + \beta_{\mathbf{r}, \mathbf{r}_a} \mathbf{Q} \quad (18)$$

$$i\frac{\partial \mathbf{Q}}{\partial t} = \beta_{\mathbf{r}, \mathbf{r}_a} (\mu_0^{1/2} \mathbf{H}) + \omega_a \mathbf{Q},$$

where $\beta_{\mathbf{r}, \mathbf{r}_a} = \beta \delta_{\mathbf{r}, \mathbf{r}_a}$, $\delta_{\mathbf{r}, \mathbf{r}_a}$ is the Kronecker symbol and β is the coupling strength between the antenna emitted wave and the magnetic field.

Finally we turn our attention to the initial conditions. The initial state vector of Eq. (15) is

$$\psi(\mathbf{r}, 0) = \psi_0 = \begin{bmatrix} \epsilon_0^{1/2} \mathbf{E}_0 \\ \mu_0^{1/2} \mathbf{H}_0 \\ 0 \\ 0 \end{bmatrix}. \quad (19)$$

Inclusion of the antenna coupling Eq. (18) adds to the initial state ψ_0 the term $\mathbf{Q}(\mathbf{r}, 0) = \mathbf{Q}_a$. The selection of the initial vacuum electromagnetic field profiles is dictated by the satisfaction of the divergence set of Maxwell equations.

$$\nabla \cdot \mathbf{D}_0 = \nabla \cdot \mathbf{E}_0 = 0, \quad \nabla \cdot \mathbf{B}_0 = 0. \quad (20)$$

In that way, the divergence Maxwell equations are guaranteed to be satisfied for $t > 0$ along with $\nabla \cdot \mathbf{J}_{cj} = 0$ from the charge continuity equation in the continuum limit.

D. Trotter Product Evolution Approximation

Application of QLA or any other quantum protocol for simulation of electromagnetic wave propagation in a cold inhomogeneous magnetized plasma requires a decomposition of the \hat{D} operator in Eq.(15) into simpler matrices,

$$\hat{D} = \hat{D}_{vac} + \sum_{j=i,e} [\hat{D}_{\omega_{pj}} + \hat{D}_{\omega_{cj}}], \quad (21)$$

with

$$\hat{D}_{vac} = -\frac{c}{2}(I_{2 \times 2} + \hat{\sigma}_z) \otimes \hat{\sigma}_y \otimes \nabla \times \quad (22)$$

$$\hat{D}_{\omega_{pi}} = \frac{1}{2} \hat{\sigma}_y \otimes (I_{2 \times 2} + \hat{\sigma}_z) \otimes \omega_{pi} \quad (23)$$

$$\hat{D}_{\omega_{pe}} = \frac{1}{2} (\hat{\sigma}_x \otimes \hat{\sigma}_y + \hat{\sigma}_y \otimes \hat{\sigma}_x) \otimes \omega_{pe} \quad (24)$$

$$\hat{D}_{\omega_{ci}} = \frac{1}{4} (I_{2 \times 2} - \hat{\sigma}_z) \otimes (I_{2 \times 2} + \hat{\sigma}_z) \otimes \omega_{ci} \hat{S}_z \quad (25)$$

$$D_{\omega_{ce}} = \frac{1}{4} (I_{2 \times 2} - \hat{\sigma}_z) \otimes (I_{2 \times 2} - \hat{\sigma}_z) \otimes \omega_{ce} \hat{S}_z. \quad (26)$$

For simplicity let us assume that all quantities are only x -dependent, rendering our model 1D. The inclusion of y - and z -dependence is straightforward, following the usual Alternate Direction Iteration (ADI) Cartesian integration procedure with no extraneous couplings of the respective quantum operators. Then, the curl operator in Eq.(22) reads

$$\nabla \times = \hat{S}_x \hat{p}_x, \quad \hat{S}_x = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -i \\ 0 & i & 0 \end{bmatrix}, \quad \hat{p}_x = -i \frac{\partial}{\partial x}. \quad (27)$$

Trotterizing the total unitary evolution $e^{-i\delta t \hat{D}}$ whose components are given in Eqs.(21)-(26) we obtain

$$\psi(\mathbf{r}, \delta t) = e^{-i\delta t \hat{D}_{vac}} \prod_{j=i,e} e^{-i\delta t \hat{D}_{\omega_{pj}}} e^{-i\delta t \hat{D}_{\omega_{cj}}} \psi_0 + O(\delta t^2). \quad (28)$$

Each of the exponential operators in Eq.(28) can be written as a product of unitary operators based on the their tensor-fold Pauli structure. Specifically, we have the following diagonalization relations for the $\hat{\sigma}_y, \hat{\sigma}_x, \hat{S}_x, \hat{S}_z$ matrices

$$\begin{aligned} \hat{\sigma}_x &= \hat{H} \hat{\sigma}_z \hat{H}, & \hat{\sigma}_y &= \hat{H}_y \hat{\sigma}_z \hat{H}_y, \\ \hat{S}_x &= \hat{H}_y^{(x)} \hat{\sigma}_z^{(x)} \hat{H}_y^{(x)}, & \hat{S}_z &= \hat{H}_y^{(z)} \hat{\sigma}_z^{(z)} \hat{H}_y^{(z)}, \end{aligned} \quad (29)$$

where \hat{H} is the unitary Hadamard gate, \hat{H}_y is the unitary variant of Hadamard gate that diagonalizes $\hat{\sigma}_y$ whereas the unitary set of matrices $\hat{H}_y^{(x)}, \hat{H}_y^{(z)}$ and Hermitian $\hat{\sigma}_z^{(x)}, \hat{\sigma}_z^{(z)}$ are the three-dimensional extensions of \hat{H}_y and $\hat{\sigma}_z$ for x and z axes respectively,

$$\begin{aligned} \hat{H} &= \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}, & \hat{H}_y &= \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & -i \\ i & -1 \end{bmatrix}, & \hat{H}_y^{(x)} &= \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & -i \\ 0 & i & -1 \end{bmatrix}, \\ H_y^{(z)} &= \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & -i & 0 \\ i & -1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, & \hat{\sigma}_z^{(x)} &= \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{bmatrix}, & \hat{\sigma}_z^{(z)} &= \begin{bmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{bmatrix}. \end{aligned} \quad (30)$$

This enables us to express the unitary exponential of op-

erators (22)-(26) using the identities:

$$e^{-i\delta t \hat{V}_1 \hat{A} \hat{V}_1^\dagger \otimes \hat{V}_2 \hat{B} \hat{V}_2^\dagger} = (\hat{V}_1 \otimes \hat{V}_2) e^{-i\delta t \hat{A} \otimes \hat{B}} (\hat{V}_1^\dagger \otimes \hat{V}_2^\dagger), \quad (31)$$

$$e^{-i\delta t I_{2 \times 2} \otimes \hat{A}} = I_{2 \times 2} \otimes e^{-i\delta t \hat{A}}, \quad (32)$$

$$e^{-i\frac{\theta}{2} \hat{\sigma}_i \otimes \hat{A}} = I_{2 \times 2} \otimes \cos(\hat{A}\theta/2) - i\hat{\sigma}_i \sin(\hat{A}\theta/2). \quad (33)$$

Therefore, the exponential operator $e^{-i\delta t \hat{D}_{vac}}$ can be written

$$e^{-i\delta t \hat{D}_{vac}} = \hat{C}_{vac} \hat{S} \hat{C}_{vac} \quad (34)$$

where the unitary collision operator \hat{C}_{vac} has the form

$$\hat{C}_{vac} = I_{2 \times 2} \otimes \hat{H}_y \otimes \hat{H}_y^{(x)}, \quad (35)$$

and the advection operator in x -direction:

$$\hat{S} = \exp\left\{i(I_{2 \times 2} + \hat{\sigma}_z) \otimes \hat{\sigma}_z \otimes \hat{\sigma}_z^{(x)} c\delta t \hat{p}_x / 2\right\}. \quad (36)$$

Similarly, we express the rest of the operators in the Trotterized evolution Eq.(28) as follows

$$e^{-i\delta t \hat{D}_{\omega_{pi}}} = \hat{C}_{\omega_{pi}} (\hat{\mathcal{R}}_z^{(pi)} \otimes I_{3 \times 3}) \hat{C}_{\omega_{pi}}, \quad (37)$$

where $\theta_{pi} = \omega_{pi} \delta t$, $\hat{C}_{\omega_{pi}}$ is the collision operator

$$\hat{C}_{\omega_{pi}} = \hat{H}_y \otimes I_{2 \times 2} \otimes I_{3 \times 3} \quad (38)$$

and the $\hat{\mathcal{R}}_z^{(pi)}$ operator is defined through identity (33) which in principle represents a functional $\hat{R}_i(\cdot)$ rotations,

$$\hat{\mathcal{R}}_z^{(pi)} = [\hat{R}_z(\theta_{pi}) \otimes I_{2 \times 2}] \hat{R}_z(\hat{\sigma}_z \theta_{pi}). \quad (39)$$

For $e^{-i\delta t \hat{D}_{\omega_{pe}}}$ we obtain

$$e^{-i\delta t \hat{D}_{\omega_{pe}}} = \hat{C}_{\omega_{pe}}^{(1)} (\hat{\mathcal{R}}_z^{(pe)} \otimes I_{3 \times 3}) \hat{C}_{\omega_{pe}}^{(1)} \hat{C}_{\omega_{pe}}^{(2)} (\hat{\mathcal{R}}_z^{(pe)} \otimes I_{3 \times 3}) \hat{C}_{\omega_{pe}}^{(2)} \quad (40)$$

with

$$\hat{C}_{\omega_{pe}}^{(1)} = \hat{H} \otimes \hat{H}_y \otimes I_{3 \times 3}, \quad (41)$$

$$\hat{C}_{\omega_{pe}}^{(2)} = \hat{H}_y \otimes \hat{H} \otimes I_{3 \times 3}, \quad (42)$$

$$\hat{\mathcal{R}}_z^{(pe)} = \hat{R}_z(\hat{\sigma}_z \theta_{pe}). \quad (43)$$

We now move to the terms containing the cyclotron angle θ_{cj} ,

$$e^{-i\delta t \hat{D}_{\omega_{ci}}} = \hat{C}_{\omega_{ci}} [I_{4 \times 4} \otimes \hat{R}_z^{(z)}(\theta_{ci}/2)] [I_{2 \times 2} \otimes \hat{R}_z(\hat{\sigma}_z^{(z)} \theta_{ci}/2)] \times \hat{\mathcal{R}}_z^{(1),(ci)\dagger} \hat{\mathcal{R}}_z^{(2),(ci)\dagger} \hat{C}_{\omega_{ci}}, \quad (44)$$

with

$$\hat{C}_{\omega_{ci}} = I_{2 \times 2} \otimes I_{2 \times 2} \otimes \hat{H}_y^{(z)} \quad (45)$$

and operators $\hat{R}_z^{(z)}(\theta_{ci}/2)$, $\hat{\mathcal{R}}_z^{(1),(ci)}$, $\hat{\mathcal{R}}_z^{(2),(ci)}$ representing z -rotation based on the 3×3 $\hat{\sigma}_z^{(z)}$ matrix and functional z -rotations respectively,

$$\hat{R}_z^{(z)}(\theta_{ci}/2) = e^{-i\frac{\theta_{ci}}{4} \hat{\sigma}_z^{(z)}}, \quad (46)$$

$$\hat{\mathcal{R}}_z^{(1),(ci)\dagger} = e^{i\frac{\theta_{ci}}{4} \hat{\sigma}_z \otimes I_{2 \times 2} \otimes \hat{\sigma}_z^{(z)}}, \quad (47)$$

$$\hat{\mathcal{R}}_z^{(2),(ci)\dagger} = e^{i\frac{\theta_{ci}}{4} \hat{\sigma}_z \otimes \hat{\sigma}_z \otimes \hat{\sigma}_z^{(z)}}. \quad (48)$$

Finally,

$$e^{-i\delta t \hat{D}_{\omega_{ce}}} = \hat{C}_{\omega_{ce}} [I_{4 \times 4} \otimes \hat{R}_z^{(z)}(\theta_{ce}/2)] [I_{2 \times 2} \otimes \hat{R}_z^\dagger(\hat{\sigma}_z^{(z)} \theta_{ce}/2)] \times \hat{\mathcal{R}}_z^{(1),(ce)\dagger} \hat{\mathcal{R}}_z^{(2),(ce)} \hat{C}_{\omega_{ce}}. \quad (49)$$

It is important to note that after we have made the somewhat standard leading-order Trotterized approximation to the total unitary evolution operator in Eq.(15), the evaluations of all the operators in Eqs.(34)-(49) are exact and no further approximations have been made.

Consequently, the fully unitary evolution sequence reads

$$\psi(\mathbf{r}, \delta t) = \hat{C}_{vac} \hat{S} \hat{C}_{vac} \hat{C}_{\omega_{pi}} (\hat{\mathcal{R}}_z^{(pi)} \otimes I_{3 \times 3}) \hat{C}_{\omega_{pi}} \hat{C}_{\omega_{pe}}^{(1)} (\hat{\mathcal{R}}_z^{(pe)} \otimes I_{3 \times 3}) \hat{C}_{\omega_{pe}}^{(1)} \hat{C}_{\omega_{pe}}^{(2)} (\hat{\mathcal{R}}_z^{(pe)} \otimes I_{3 \times 3}) \hat{C}_{\omega_{pe}}^{(2)} \hat{C}_{\omega_{ci}} [I_{4 \times 4} \otimes \hat{R}_z^{(z)}(\theta_{ci}/2)] \times [I_{2 \times 2} \otimes \hat{R}_z(\hat{\sigma}_z^{(z)} \theta_{ci}/2)] \hat{\mathcal{R}}_z^{(1),(ci)\dagger} \hat{\mathcal{R}}_z^{(2),(ci)\dagger} \hat{C}_{\omega_{ci}} \hat{C}_{\omega_{ce}} [I_{4 \times 4} \otimes \hat{R}_z^{(z)}(\theta_{ce}/2)] [I_{2 \times 2} \otimes \hat{R}_z^\dagger(\hat{\sigma}_z^{(z)} \theta_{ce}/2)] \hat{\mathcal{R}}_z^{(1),(ce)\dagger} \hat{\mathcal{R}}_z^{(2),(ce)} \hat{C}_{\omega_{ce}} \psi_0. \quad (50)$$

E. Quantum encoding and complexity analysis

Implementation of the Trotterized unitary product formula Eq.(50) in a digital quantum computer requires spatial discretization. We pursue a qubit lattice algorithm (QLA) discretization where the evolution (50) transcends into an interleaved sequence of non-commuting QLA collision \hat{C} and streaming \hat{S} operators that recover the Schrodinger-Maxwell equation (15) to a second order diffusion scheme, $\delta t \sim \delta^2$, $\delta x \sim \delta$. The advantage of this description stems from treating the advection operator \hat{S}

in Eq.(36), through the QLA streaming operators \hat{S} 's, enabling an efficient quantum implementation^{15-17,27}. The rest of the participating operators in Eq.(50) will comprise the QLA collision operators \hat{C} .

Ultimately, to implement the QLA evolution derived from Eq.(50) onto a quantum computer we must express the participating operators into elementary quantum gates acting on a set of qubits. We will use two qubit registers. The first encodes the amplitude dimensionality of the state vector ψ in Eq.(15), hence containing $n_i = 4$ qubits with $\{|i\rangle\}$ basis. The second register labels

the spatial discretization. For a one-dimensional lattice with N nodes and a discretization step δ , we will need $n_p = \log_2 N$ qubits with basis $\{|p\rangle\}$. Therefore, a total number of $n_{total} = n_p + 4$ qubits are required for the complete description of the state ψ .

Then, the qubit encoding of the state vector ψ reads,

$$|\psi\rangle = \sum_{p=0}^{N-1} \sum_{i=0}^{11} \psi_{0ip} |i\rangle |p\rangle, \quad (51)$$

with amplitudes ψ_{ip} characterize the i -component of the state vector ψ in the lattice site p . The quantum state $|\psi\rangle$ is normalized to the square root of the initial (constant) electromagnetic energy so that $\sum_{i,p} |\psi_{0ip}|^2 = 1$.

Establishing the required circuit width (total number of qubits) for the quantum encoding of our state, we proceed to analyze the decomposition scaling (circuit depth) of operators in Eq.(50) into simple one-qubit and CNOT gates to n_{total} . All the unitary collision \hat{C} 's operators are in tensor product of elementary single-qubit gates like the Hadamard gate \hat{H} and rotation gate $\hat{H}_y = \hat{\sigma}_z \hat{R}_x(\pi/2)$ whereas the $\hat{H}_y^{(z)}, \hat{H}_y^{(x)}$ two-level gates can be easily implemented within simple, one-qubit gates. In addition, those operators act solely in the 4-qubit amplitude register $\{|i\rangle\}$, resulting to constant scaling and can be implemented in the worst case scenario as $O(k \cdot 4^2)$, $k \in \mathcal{N}$. The integer k accounts for the total number of collision operators \hat{C} in Eq.(50). As far as the unitary rotation operators which contain the plasma inhomogeneity are concerned, they are all diagonal and can be decomposed into simpler two-level z -rotations or directly implemented within $O(m \cdot 2^{n_{total}+1})$ CNOTs and single-qubit gates³⁴. As previous, the natural number m now accounts for the total number of those diagonal inhomogeneous operators in Eq.(50). Finally, the QLA streaming \hat{S} operators offer the advantage of implementing the associated advective operator \hat{S} as a quantum walk¹⁶. The explicit circuit implementation of this quantum walk into a quantum computer is presented in Refs.[15], [17]. The QLA streaming operators act only in the spatial discretization register $\{|p\rangle\}$, controlled by the $\{|i\rangle\}$ qubits, so based on the results of Refs.[15] and [17] they are expected to scale as $O(l \cdot n_p^2)$, $l \in \mathcal{N}$.

Consequently, the total quantum implementation scaling of the QLA discretization scheme of unitary evolution (50) is expected to be $O(32m \cdot 2^{n_p} + l \cdot n_p^2 + 16k)$. For fusion relevant applications the inhomogeneity plasma profile is localized, enabling us to reduce the encoding cost of the inhomogeneous diagonal rotation operators to $O[\text{poly}(n_p)]$ which in turn implies that the total implementation cost of our algorithm scales polynomially $O[\text{poly}(n_p)]$ with the number of qubits in the p -register. This polynomial scaling promotes QLA as prominent candidate for implementation in real quantum hardware in the near future.

F. Discussion

Comparing the Schrodinger representation of Maxwell equations for inhomogeneous non-dispersive media Eq.(1) with Eq.(15) for the magnetized plasma, it seems that the latter supports more complexity due to the dimensionality of the state vector ψ . But, in contrast with the optical case where the respective spatial displacement operator interferes with the inhomogeneity of the refractive index (see Eq.(2)) the respective exponential of operator \hat{D}_{vac} in Eq.(22) is explicitly decomposed without implicit dependence on the inhomogeneity plasma profile which is reflected in the plasma frequencies. As a consequence, the expected QLA will be free of the non-unitary potential operators \hat{V} such those introduced in Refs.[18–20], resulting in a fully unitary product sequence similar to that of a homogeneous medium²¹.

Subsequently, a vacuum QLA sequence denoted as \hat{U}_X^{vac} can be immediately employed to calculate the term $e^{-i\delta t \hat{D}_{vac}}$ in the Trotterized evolution approximation of $e^{-i\delta t \hat{D}}$,

$$\begin{aligned} e^{-i\delta t \hat{D}} &= e^{-i\delta t \hat{D}_{disp}} e^{-i\delta t \hat{D}_{vac}} + O(\delta t^2) \\ &= e^{-i\delta t \hat{D}_{disp}} \hat{U}_X^{vac} + O(\delta t^2). \end{aligned} \quad (52)$$

Implementation of the dispersive part $e^{-i\delta t \hat{D}_{disp}}$, where $\hat{D}_{disp} = \sum_{j=i,e} \hat{D}_{\omega_{pj}} + \hat{D}_{\omega_{cj}}$ can be performed in parallel with the QLA. The main advantage of this approximation is that we can decide whether to classically compute the $\hat{U}_X^{vac} \psi_0$, store the information and proceed with a follow up quantum computation for the $e^{-i\delta t \hat{D}_{disp}}$ term resulting in a hybrid computation, or purely quantum computing the whole sequence based on the quantum encoding of QLA as described in Sec.IIE.

In addition, the unitary QLA derived from evolution sequence (50) conserve the extended electromagnetic energy Eq.(16) and the divergence conditions. Thus, our full-wave scheme can be extended beyond the usual plane-wave or monochromatic wave approximations. This is very important in the case of fusion plasmas where the RF waves that are used for plasma heating and current drive are wave-packets that are localized in space and of finite duration in time. The interaction of the inhomogeneity plasma profile with the envelope of the carrier wave, as well as with the individual components that a spatially confined beam consists of, will lead to complex electromagnetic structures that will affect the current densities in the dispersive plasma. More importantly, those transport effects correspond to energy transfer from the initial electromagnetic fields to the current density fields and can be explicitly measured due to Eq.(16) which describes the extended electromagnetic energy. Hence, examination of wave packet propagation in plasmas is relevant to realistic fusion experiments. For instance, an initial X-wave polarization $\mathbf{E}_0 = E_y(k_x x) \hat{y}$ profile, the scattering from a two dimensional $x-y$ plasma inhomogeneity will generate the electromag-

netic fields $\mathbf{E} = E_x(k_x x, k_y y, \omega_X t)\hat{\mathbf{x}} + E_y(k_x x, k_y y, \omega_X t)\hat{\mathbf{y}}$ and $\mathbf{B} = B_z(k_x x, k_y y, \omega_X t)\hat{\mathbf{z}}$ but most importantly will produce the conductivity current density $\mathbf{J}_{cj} = J_{xcj}(k_x x, k_y y, \omega_X t)\hat{\mathbf{x}} + J_{ycj}(k_x x, k_y y, \omega_X t)\hat{\mathbf{y}}$ to satisfy $\nabla \cdot \mathbf{E} = \nabla \cdot \mathbf{B} = \nabla \cdot \mathbf{J}_{cj} = 0$.

Given the fact that the QLA scales linearly with the number of processors and its quantum variant is probably expected to scale as $O[\text{poly}(n_p)]$, it is evident that our considerations pose a strong alternative to the cost-inefficient FDTD methods, particularly in 2D and 3D.

On the other hand, it may be necessary to further manipulate the evolution sequence (50) for an optimized QLA to be produced.^{23,28} Therefore, considerable research is required before applying the QLA for simulation of wave propagation into a plasma characterized by fusion-reactor parameters.

III. EXAMPLE: QLA FOR SCATTERING FROM 2D SCALAR NON-DISPERSIVE DIELECTRIC OBJECTS

Although the analytical and algorithmic establishments in Sec. II should result in an efficient quantum computer code for electromagnetic wave propagation in cold inhomogeneous magnetized plasmas, much work remains to be done in optimizing the qubit presentation of a QLA code for Eq. (50) before tackling the propagation of such fusion relevant RF wave-packets in plasma.

It is thus instructive to first investigate our Maxwell QLA code capabilities and behavior for the scattering of an electromagnetic pulse from a non-dispersive 2D inhomogeneous dielectric object, and we shall observe some interesting physics arising from the initial value simulations.

A. The algorithm

To showcase what a QLA sequence looks like and what we expect to obtain from the ‘‘QLAzation’’ of Eq. (50), we briefly present the algorithmic scheme for a 2D $x - y$ scattering of a wave-packet from a scalar but non-dispersive localized inhomogeneities with refractive index $n = n(x, y)$, as displayed in Fig. 1. The shape of the inhomogeneities, can be related to cylindrical filaments or smooth localized concentrations of plasma density.

In our reduced case of non-dispersive dielectric, QLA is a discrete representation of unitary representation of Maxwell equations (1) which, at a mesoscopic level, uses an appropriately chosen interleaved sequence of three non-commuting operators. Two of the operators are unitary collision and streaming operators – the collision operator entangles the on-site qubits and the streaming operator propagates the entangled state through the lattice. The gradients in the medium constitutive properties are included via a third operator referred to as a potential operator.

FIG. 1. Two different inhomogeneity refractive index profiles $1 \leq n(x, y) \leq 2$ and the electric field $E_{z0}(x)$ of the incident wave-packet. The cylinder dielectric has strong spatial gradient near the vacuum-dielectric interface, while the conic dielectric has very weak spatial gradients. In Fig. 1a these two profiles are shown superimposed. In Fig. 1b the conic dielectric is shown together with the incident wave-packet (arbitrary normalization).

For 2D $x - y$ scattering of electromagnetic fields for a scalar dielectric state vector that evolves unitarily is

$$\mathbf{q} = \begin{bmatrix} nE_x \\ nE_y \\ nE_z \\ \mu_0^{1/2} H_x \\ \mu_0^{1/2} H_y \\ \mu_0^{1/2} H_z \end{bmatrix} = \begin{bmatrix} q_0 \\ q_1 \\ q_2 \\ q_3 \\ q_4 \\ q_5 \end{bmatrix}. \quad (53)$$

In (diagonal) tensor dielectric media one would simply have $q_0 \rightarrow n_x E_x$, $q_1 \rightarrow n_y E_y$, $q_2 \rightarrow n_z E_z$.

The decomposition of the electromagnetic Schrodinger

equation (1) in Cartesian components is

$$\begin{aligned}\frac{\partial q_0}{\partial t} &= \frac{1}{n} \frac{\partial q_5}{\partial y}, & \frac{\partial q_1}{\partial t} &= \frac{1}{n} \frac{\partial q_5}{\partial x}, & \frac{\partial q_2}{\partial t} &= \frac{1}{n} \left[\frac{\partial q_4}{\partial x} - \frac{\partial q_3}{\partial y} \right], \\ \frac{\partial q_3}{\partial t} &= \frac{\partial(q_2/n)}{\partial y}, & \frac{\partial q_4}{\partial t} &= \frac{\partial(q_2/n)}{\partial x}, \\ \frac{\partial q_5}{\partial t} &= -\frac{\partial(q_1/n)}{\partial x} + \frac{\partial(q_0/n)}{\partial n_y}.\end{aligned}\quad (54)$$

For the discrete QLA, using the Alternating Directions Implicit (ADI) integration, the unitary collision operators in the x and y directions are

$$\hat{C}_X = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & \cos \theta_0 & 0 & 0 & 0 & -\sin \theta_0 \\ 0 & 0 & \cos \theta_0 & 0 & -\sin \theta_0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & \sin \theta_0 & 0 & \cos \theta_0 & 0 \\ 0 & \sin \theta_0 & 0 & 0 & 0 & \cos \theta_0 \end{bmatrix}, \quad (55)$$

$$\hat{C}_Y = \begin{bmatrix} \cos \theta_0 & 0 & 0 & 0 & 0 & \sin \theta_0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & \cos \theta_0 & \sin \theta_0 & 0 & 0 \\ 0 & 0 & -\sin \theta_0 & \cos \theta_0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ -\sin \theta_0 & 0 & 0 & 0 & 0 & \cos \theta_0 \end{bmatrix}. \quad (56)$$

with collision angle $\theta_0 = \delta/4n$. The form of \hat{C}_X can be readily discerned from the coupling of the $\frac{\partial}{\partial t}$ with $\frac{\partial}{\partial x}$ derivatives in (54): $q_1 - q_5$, and $q_2 - q_4$, as well as the respective collision angle. Similarly for the unitary matrix \hat{C}_Y .

We now define the unitary streaming operator \hat{S}_{ij} which shifts the amplitudes $\{q_i, q_j\}$ one lattice unit, either in the x or in the y direction, while leaving all the other amplitudes unaffected. Then the collide-stream sequence along each direction is,

$$\begin{aligned}\hat{U}_X &= \hat{S}_{25}^{+x} \hat{C}_X^\dagger \hat{S}_{25}^{-x} \hat{C}_X \hat{S}_{14}^{-x} \hat{C}_X^\dagger \hat{S}_{14}^{+x} \hat{C}_X \hat{S}_{25}^{-x} \hat{C}_X \hat{S}_{25}^{+x} \hat{C}_X^\dagger \hat{S}_{14}^{+x} \hat{C}_X \hat{S}_{14}^{-x} \hat{C}_X^\dagger \\ \hat{U}_Y &= \hat{S}_{25}^{+y} \hat{C}_Y^\dagger \hat{S}_{25}^{-y} \hat{C}_Y \hat{S}_{03}^{-y} \hat{C}_Y^\dagger \hat{S}_{03}^{+y} \hat{C}_Y \hat{S}_{25}^{-y} \hat{C}_Y \hat{S}_{25}^{+y} \hat{C}_Y^\dagger \hat{S}_{03}^{+y} \hat{C}_Y \hat{S}_{03}^{-y} \hat{C}_Y^\dagger.\end{aligned}\quad (57)$$

It should be noted that the first set of four collide-stream operators in \hat{U}_X and \hat{U}_Y would yield (54) to first order in δ . An in-depth analysis on derivation of the QLA sequences Eq.(57) can be found in Refs.[18–20, 23, and 28] and in references therein.

The terms in (54), containing the derivatives of the refractive index, are recovered through the following potential operators

$$\hat{V}_X = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & -\sin \beta_0 & 0 & \cos \beta_0 & 0 \\ 0 & \sin \beta_0 & 0 & 0 & 0 & \cos \beta_0 \end{bmatrix} \quad (58)$$

and

$$\hat{V}_Y = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & \cos \beta_1 & \sin \beta_1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ -\sin \beta_1 & 0 & 0 & 0 & 0 & \cos \beta_1 \end{bmatrix}. \quad (59)$$

The angles $\theta_0 = \delta/4n$, $\beta_0 = \delta^2 \frac{\partial n / \partial x}{n^2}$, and $\beta_1 = \delta^2 \frac{\partial n / \partial y}{n^2}$, that appearing in matrices (55), (56), (58), and (59) are chosen so that the discretized system reproduces (54) to order $O(\delta^2)$.

The evolution of the state vector \mathbf{q} from time t to $t + \Delta t$

is given by,

$$\mathbf{q}(t + \Delta t) = \hat{V}_Y \hat{V}_X \hat{U}_Y \hat{U}_X \mathbf{q}(t). \quad (60)$$

Note that the external potential operators \hat{V}_X, \hat{V}_Y , as given above, are not unitary. Quantum implementation of the non-unitary potential operators \hat{V}_X, \hat{V}_Y can be handled using the Linear Combination of Unitaries (LCU) method.³⁵ We direct the reader to Ref. [15] for a detailed discussion on the quantum circuit implementation of these QLA non-unitary operators.

A detailed analysis of the QLA for the more general case of a bi-axial medium along with simulation results for scattering of Gaussian pulses can be found in Ref. [23].

B. QLA simulation results

In all simulations, the total energy is conserved to the seventh significant digit. A numerical study of errors with respect to spatial resolution was performed in Ref.[27]. It indeed verified that the QLA performs better than 2nd order accuracy. This scaling was further verified in Ref.[36] for spinor BECs. In addition, from current discrete simulation 2D QLA runs^{21,23}, it appears that divergence cleaning is not required as QLA divergence errors are spatially localized and do not accumulate. We also reiterate that in applications of QLA to nonlinear spinor

Bose-Einstein condensates, the QLA produced an algorithm that was ideally parallelized to all available cores on a classical supercomputer (over 750,000 cores on the now-retired IBM Blue Gene/*Mira* supercomputer at Argonne).

(a)

(b)

FIG. 2. QLA scattering simulation of z -component of an electromagnetic pulse, E_{z0} off a dielectric inhomogeneity in the shape of a cone (Fig.2a), versus a cylindrical dielectric (Fig.2b). The perspective is looking down the z -axis onto the x - y plane. The full-wave simulation for the wave-cylinder encounter reveals strong initial reflection phenomena whereas the reflection is very weak in the cone case. This differentiation in the wave behavior is directly related to the steepness of the inhomogeneity gradient. The weak reflected wave from the cone corresponds to asymptotic WKB type of solution.

The initial electromagnetic wave-packet $\mathbf{u}_0 = (E_{z0}(x), -B_{y0}(x))^T$ is a Gaussian envelope with internal oscillations, Fig.1b. The wave-packet propagates in the x -direction, from a vacuum $n = 1$ towards a localized dielectric inhomogeneous object with $n_{max}(x, y) = 2$. This polarization satisfies the initial divergence condi-

tions. As the 1D vacuum wave-packet interacts with the 2D refractive index of the dielectric. the B_y field now becomes 2D, with $B_y(x, y, t)$. This self-consistently generates a $B_x(x, y, t)$ so that $\nabla \cdot \mathbf{B} = 0$ as well as a 2D $E_z(x, y, t)$. Throughout the QLA scattering simulation, $\nabla \cdot \mathbf{B}$ is monitored and is non-zero in very small isolated spatial regions with some time instants in which $\max_{x,y} |\nabla \cdot \mathbf{B} / \mathbf{B}_0| \leq 0.006$. $\nabla \cdot \mathbf{D}$ is identically zero throughout the simulation. [For initial $E_{y0}(x)$ -polarization, 2D QLA simulations retain $\nabla \cdot \mathbf{B} = 0$ identically zero for all time.]

In Fig.2, the wave-packet has interacted with the dielectric object. The viewpoint is looking down from the z -axis onto the x - y plane. The apex of the cone is seen as a white dot, while the interior of the dielectric cylinder is in a somewhat darker color than the surrounding vacuum. In the case of a dielectric cone, Fig.2a, there is a mild slowing down of that part of the packet that is around the apex of the cone - since the phase velocity is reduced to $c/n(x, y)$. But more importantly, one does not see any reflected part of the packet from the slowly varying boundary region between vacuum and dielectric. Basically the propagation is WKB-like. On the other hand there are immediate reflection fronts emitted back into the vacuum from the interaction of the wave-packet's oscillation peaks with the steep refractive index gradients in the boundary region of vacuum and cylinder dielectric, Fig.2b. There is also considerable retardation in the oscillation peaks within the dielectric cylinder as the refractive index away from the boundaries are $n = 2$.

As mentioned earlier, the transmitted component of the initial wave-packet propagates into the respective dielectrics with phase velocity

$$v_{ph} = \frac{c}{n(x, y)} \quad (61)$$

because there is no dispersion in the media. However, the wave crests and the envelope along the y -direction possess different phase velocities during their propagation in the dielectric resulting in a lag between the interior and outer wave components. Ultimately, both dielectrics exhibit complex diffraction patterns outside the dielectric as well as bounded eigenmodes within the latter. This behavior is clearly depicted in Fig.3.

As the bounded modes within the dielectric approach the vacuum boundary, the rapid change in the cylindrical dielectric object produces a secondary internal reflection that propagates back inside the cylinder. For the cone case, the slowly varying transition between the different regions contributes a negligible secondary reflection. Those secondary reflections, along with the secondary propagating wave-fronts in the vacuum region are presented in Fig.4.

The back and forth succession from Fig.4 to Fig.2 through higher order internal reflections in the cylindrical dielectric results in a radiating temporal pattern. It should be reminded that QLA is an initial value solver giving the temporal (and transient) evolution of the

(a)

(b)

FIG. 3. The propagation of the transmitted wave within the conical and cylindrical dielectrics. The wave propagation is now distorted because the initial wave crests along the y -axis diffract on the dielectric boundary. In both cases, Figs.3a, 3b, transmitted bounded modes are observed towards the exit point to vacuum.

scattered field without the introduction of any internal boundary conditions to handle vacuum-dielectric effects. Even though the simulations are for non-dispersive dielectrics they reveal that the QLA accurately grasps the interconnection of the transient behavior of waves with the inhomogeneity profile. Extending those considerations to inhomogeneous fusion plasma will provide insights in the temporal evolution of the electromagnetic fields and the species current densities (see the state vector ψ in Eq.(15)) that potentially could affect the heating efficiency and the energy transfer.

(a)

(b)

FIG. 4. The absence of internal reflections from the conical dielectric Fig.4a versus the internal reflections from the cylindrical dielectric Fig.4b. Similar to the behavior of the primary reflections in Fig.2 the inhomogeneity gradient of the dielectrics plays a pivotal role on the strength of the internal reflection.

IV. CONCLUSIONS

The contributions of this paper are: (1) the analytical formulation of Maxwell equations in a magnetized plasma, Eq.(15), as a Schrodinger equation, and (2) a fully unitary QLA representation of this augmented Schrodinger equation indicating a polynomial scaling for implementation in a quantum computer that can be tested on present day classical computers.

The augmented Schrodinger representation has advantages over the standard Helmholtz formulation^{37,38} both in the regularity of the spatial derivative of the fields as well as in the construction of formal solutions. The Hermitian structure of the full operator \hat{D} permits a nor-

mal mode decomposition of the solution in terms of the eigenfunctions $\phi(\mathbf{r}, \lambda)$ of \hat{D} operator with λ being the respective eigenvalues. This is very important in cases where the inhomogeneous plasma profile does not possess a simple symmetry. In addition, the unitary evolution of Eq.(15) explicitly preserves an extended electromagnetic energy integral (16) beyond the usual Landau and Brillouin approximations³⁹.

While various quantum simulation schemes can be devised for the solution of the augmented Schrodinger equation (15) for wave propagation in a cold magnetized plasma we are currently pursuing a QLA scheme by expressing the energy preserving evolution as the unitary product formula (50). This decomposition is deemed suitable for construction of a fully unitary QLA, which no longer requires the introduction of potential operators, and their subsequent quantum encoding. Our findings support that the produced QLA sequence of unitary collision-streaming operators could be implemented on a quantum computer with polynomial scaling in respect with the number of qubits $n_p = \log_2 N$ required to describe the N lattice sites.

To benchmark the capabilities of QLA we present here the two dimensional scattering of a wave-packet from either a cylindrical or a conical scalar, inhomogeneous non-dispersive dielectrics. For the conic dielectric there are weak spatial gradients in the layer connecting the vacuum to the dielectric. As a result, there is negligible reflection at the first encounter of the wave packet with the dielectric and then following the interaction with the steep cone apex there is no internal reflections within the dielectric. This results in a simple scattered field from the cone. However, for the cylindrical dielectric, the sharp (but continuous) gradient in the layer connecting the dielectric to the vacuum, yields an immediate reflected wave front from the first interaction of the wave packet with the dielectric followed by subsequent reflection/transmission of the wave packet at the dielectric-vacuum layer. This leads to quite complex interference in the scattered fields.

We are now exploring QLA simulations of the wave propagation in a cold magnetized (dispersive) plasma, exploiting the QLA operator splitting approach. While only the x -dependent fully unitary QLA is presented here, the use of the Alternating Direction Implicit (ADI) integration scheme will permit extensions to fully 3D simulations. Moreover, the fact that QLA is ideally parallelized on classical supercomputers together with the polynomial scaling of its quantum implementation yields a pathway for high fidelity simulation results and possibly a hybrid classical-quantum computation model.

This research was partially supported by Department of Energy grants DE-SC0021647, DE-FG0291ER-54109, DE-SC0021651, DE-SC0021857, and DE-SC0021653. This research used resources of the National Energy Research Scientific Computing Center (NERSC), a U.S. Department of Energy Office of Science User Facility located at Lawrence Berkeley National Laboratory, operated under Contract No. DE-AC02-05CH11231 using NERSC award FES-ERCAP0020430.

AUTHOR DECLARATIONS

Conflict of Interest

The authors have no conflicts to disclose.

Author Contributions

Efstathios Koukoutsis: Conceptualization (lead); Formal analysis (lead); Methodology (equal); Investigation (equal); Writing - original draft (lead); Writing - review & editing (equal). **Kyriakos Hizanidis:** Methodology (equal); Supervision (supporting); Investigation (supporting); Writing - review & editing (equal); Funding acquisition (equal). **George Vahala:** Conceptualization - QLA (lead); Methodology (equal); Investigation - QLA (lead); Visualization (equal); Writing - review & editing (equal); Funding acquisition (equal). **Min Soe:** Software - QLA MPI & Graphics routines (lead); Visualization (equal); Funding acquisition (equal). **Linda Vahala:** Data curation - data analysis (lead), Writing - review & editing (equal); Funding acquisition (equal). **Abhay K. Ram:** Methodology (equal); Investigation - physics (equal); Writing - review & editing (equal); Funding acquisition (equal).

DATA AVAILABILITY

The data that support the findings of this research are available from the corresponding author upon reasonable request.
